# Chapter 1 Introduction

---

This document shows the power consumption of the Eurotech CPU-1210 board under different memory configurations and clock settings.

The CPU-1210 is a highly integrated PC/104 CPU module with the following features:

- Fully DOS and PC/AT compatible
- Fully PC/104 version 1.0 compliant
- Static 386SX processor
- 2 Serial Ports: 16550 compatible
  - One selectable between RS232, RS422 or RS485
  - One fixed as RS232
- 1 Floppy disk (available also on the parallel port through an external adapter)
- 1 Parallel Port, (EPP, ECP or SPP)
- 1 PC/AT Keyboard interface
- 1 Standard EIDE hard drive interface.
- Selectable operating frequencies 8MHz, 12MHz, 16MHz, 20MHz, 33MHz or 40MHz
- Memory (depending on option): 2MB, 4MB or 8MB EDO DRAM
- A 32-pin socket is available for a DISK ON CHIP (DOC), PEROM, Static Ram or EPROM.

The following pages show how to reduce the power consumption of the CPU-1210.

## **Chapter 2 Power Measurements**

---

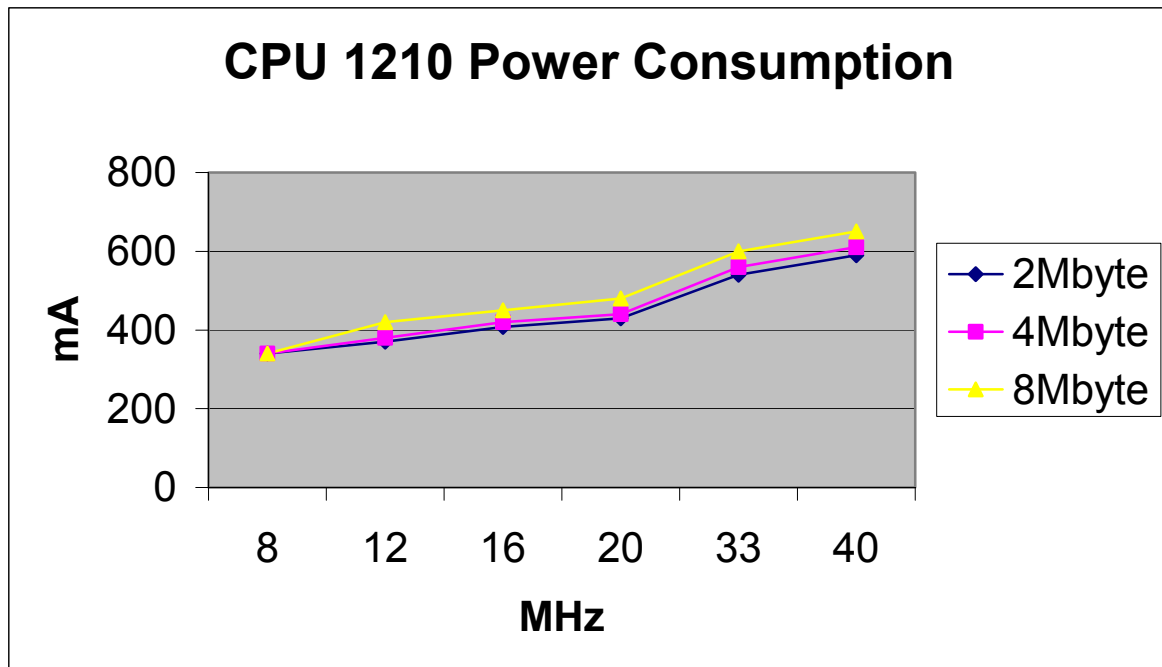

The CPU-1210 requires +5VDC  $\pm$  5% to function correctly. Supply current has been measured under all memory configurations and all available clock frequency settings.

Please note that the CPU clock frequency is set via the CPU BIOS set-up utility. Refer to the CPU-1210 user manual for additional information regarding this utility.

Following are the results of these measurements:

| Clock Frequency | On Board Memory |        |        |
|-----------------|-----------------|--------|--------|
|                 | 2 MB            | 4 MB   | 8 MB   |
| 8 MHz           | 340 mA          | 370 mA | 410 mA |
| 12 MHz          | 370 mA          | 380 mA | 420 mA |
| 16 MHz          | 408 mA          | 420 mA | 450 mA |
| 20 MHz          | 430 mA          | 440 mA | 480 mA |
| 33 MHz          | 540 mA          | 560 mA | 600 mA |
| 40 MHz          | 590 mA          | 610 mA | 650 mA |

All current measurements are  $\pm$  5mA

## **Chapter 3 Reducing CPU power consumption**

---

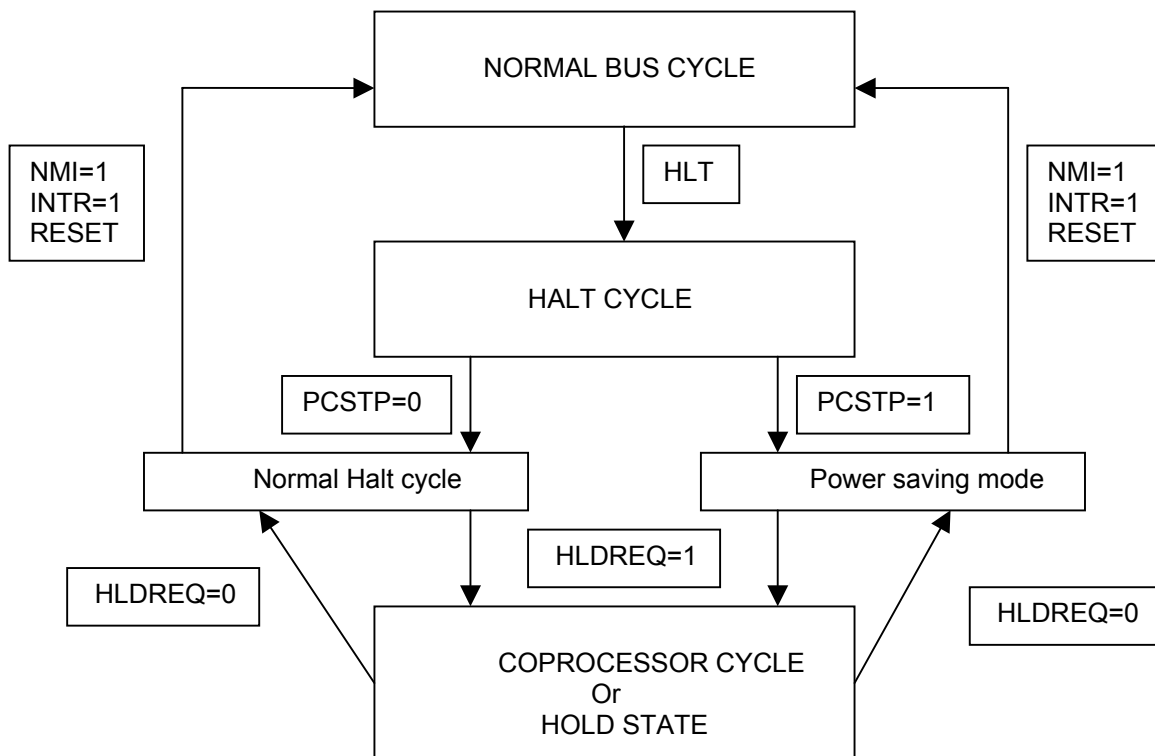

At the core of the CPU-1210 is the M6117C chip; you can easily stop the internal clock of CPU core in order to save almost 80% of its power consumption.

Due to the pure CMOS process, it will keep internal states from leaking current when Vcc is still powered on and clock has stopped.

There is one control bit called "Power Stop Clock" (PCSTP) in the internal control register, this is used to determine if M6117C is going to enter power saving mode or not.

Note that chip enters power saving mode by executing the HALT instruction, and exits with any interrupt or reset.

The following flow chart depicts power saving mode:

(This page is intentionally left blank.)

## **Chapter 4   Programming Example**

---

The following example code is used to halt the CPU and restart when the keyboard interrupt is enabled:

```
.model small
.386p

cseg segment para public 'code' use16
    org     100h
    assume cs:cseg,ds:cseg

start:  jmp  ini
old21  db  ?

ini:
    in  al,21h
    mov byte ptr cs:old21,al           ; Save old interrupt mask

    mov al,0fdh                       ; Bit 0=1 disable timer int
                                       ; Bit 1=0 enable keyb int
    out 21h,al                         ; Only Keyb interrupt enabled

    push cx
    mov cx,65000                       ; A little delay
delay:
    in  al,80h
    loop delay
    pop cx                             ; Register restore

    mov eax,00008000h
    db  0d6h,0fah,03h,02h             ; Copy EAX to CR02h register
                                       ; Bit 15 (PCSTP) =1

    hlt                               ; Stop ALIM6117C

    mov al,byte ptr cs:old21          ; Restore old mask
    out 21h,al

    mov ax,4c00h                       ; Return to DOS
    int 21h

cseg ends                               ; End
    end start
```

After this a keyboard interrupt is able to wake-up the chip

**WARNING:**

If you keep the timer interrupt enabled you'll receive an interrupt after 50mS. Be sure to disable interrupt 0, as shown in the previous piece of code!
